Chapter 1

The growth of social groups

1.1 Social groups

Two popular online platforms **Reddit** and **Meetup** are organized into different groups. On Reddit [1], users create subreddits, where they share web content and discussion on specific topics, so their interactions are online through posts and comments. The Meetup groups [2], are also topic-focused, but the primary purpose of these groups is to help users in organizing offline meetings. As meetings happen face-to-face, Meetup groups are geographically localized, so we'll focus on groups created in two towns, London and New York.

The Meetup data cover groups created from 2003, when the Meetup site was founded, until 2018, when using the Meetup API we downloaded data. We extracted the groups from London and New York that were active for at least two months. There were 4673 groups with 831685 members in London and 4752 groups with 1059632 members in New York. For each group, we got information about organized meetings and users who attended them. From there, for each user, we can find the date when the user participated in a group event for the first time; it is considered the date when the user joined a group.

The Reddit data were downloaded from https://pushshift.io/ site. This site collects posts and comments daily; data are publicly available in JSON files for each month. The selected subreddits were created between 2006 and 2011, we also filtered those active in 2017. We removed subreddits active for less than two months. The obtained dataset has 17073 subreddits with 2195677 active members. For each post, we extracted the subreddit-id, user-id and the date when the user created the post. Finally, we selected the date when each user posted on each subreddit for the first time.

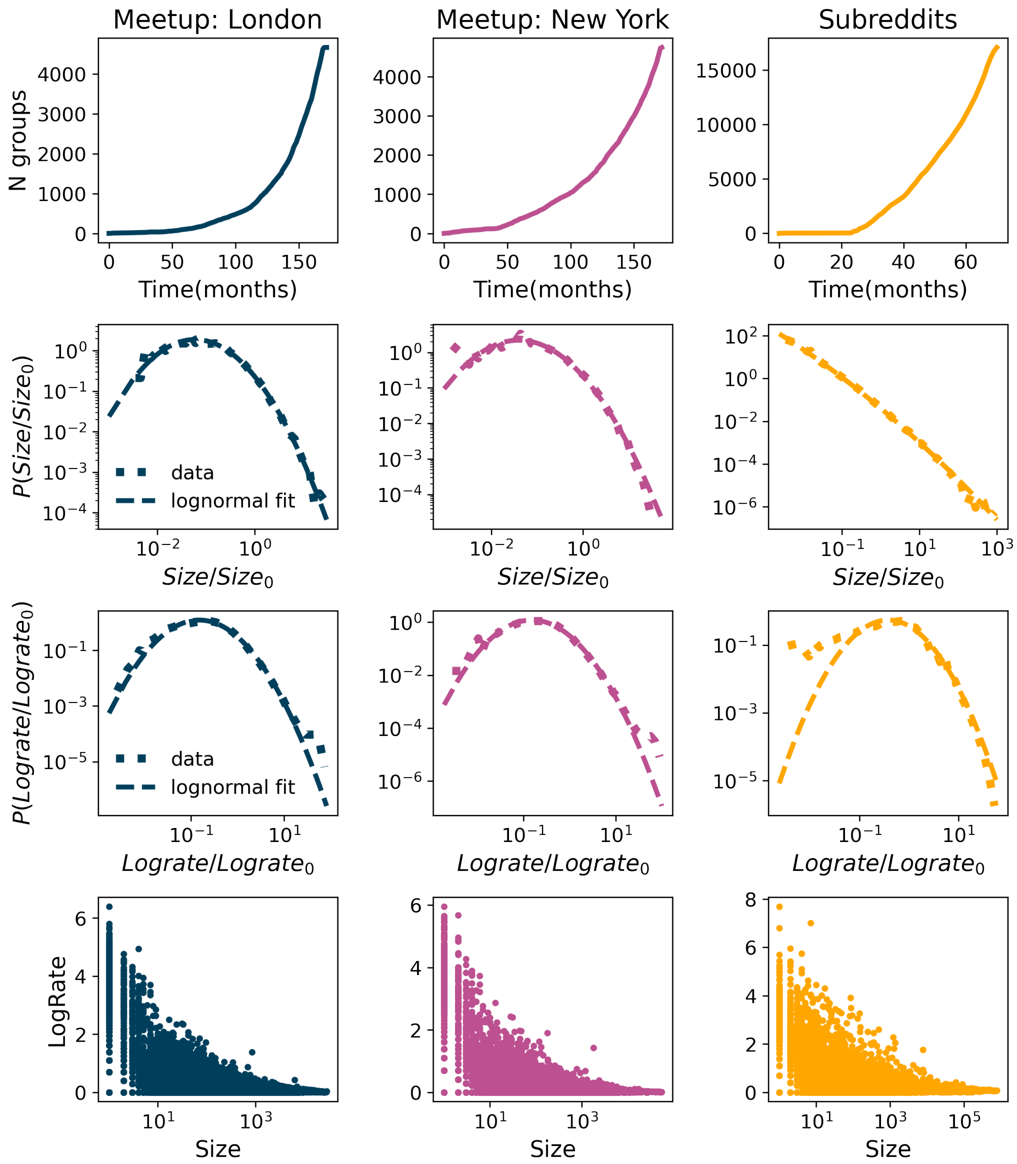
1.1.1 The empirical analysis of social groups

For each Meetup group we have information when user attended the group event, while for subreddit we have detailed data about user activity, so we can extract the information when user for the first time created a post. Those dates are considered as timestamp when user joined to group. So both datasets have the same structure: (g, u, t), where t is timestamp when user u joined group g. For each

[1] https://www.reddit.com/

[2] www.meetup.com

time step, we can calculate the number of new members in each group $N_i(t)$, and the group size $S_i(t)$. The group size at time step t is $S_i(t) = \sum_{k=t_0}^{k=t} N_i(t)$, where t_0 is month when group is created. The group size is increasing in time, as we do not have information if the user stopped to be active. Also we calculate the growth rate, as the logarithm of successive sizes $R = log(S_i(t)/S_i(t-1))$.



Meetup: London

Meetup: New York

Subreddits

Figure 1.1: The number of groups over time, normalized sizes distribution, normalized log-rates distribution and dependence of log-rates and group sizes for Meetup groups created in London from 08-2002 until 07-2017 that were active in 2017 and subreddits created in the period from 01-2006 to the 12-2011 that were active in 2017.

Even though Meetup and Reddit are different online platforms, we find some common properties of these systems; see figure 1.1. The number of groups and the number of new users grow exponentially. Still, subreddits are larger groups than Meetups. The distribution of groups sizes follows the log-normal distribution:

$$P(S) = \frac{1}{S\sigma\sqrt{2\pi}} exp(-\frac{(\ln(S)-\mu)^2}{2\sigma^2}) \tag{1.1}$$

where S is the group size and μ, and σ are parameters of the distribution. The group sizes distribution of Subreddits is a broad log-normal distribution that resembles the power law. Still, we used the loglikelihood ratio method and showed that log-normal distribution is better than the power-law. More details are given in the result section.

The simplest model that generates the lognormal distribution is multiplicative process [1]. Gibrat used this model to explain the growth of firms. The main assumption of this model is that growth rates $R = log\frac{S_t}{S_{t-\Delta t}}$ do not depend on the size S and that they are uncorrelated. Further, this imply the lognormal distribution of the sizes, while the distribution of growth rates appears to be normal distribution, [2], [3]. Figure 1.2 shows distribution of the lograte s, that follow lognormal distribution, contrary to the Gibrat law. Furthermore, lograte s depend on the group size 1.2. For these reasons the Gibrat law can not explain the growth of online social groups [4, 5].

The growth of online social groups has universal behavior. It is independent on the size of the group. If we aggregate the groups created in the same year y, and each group size normalize with average size $< S^y >$, $s_i^y = S_i^y / < S^y >$ we will find that group sizes distributions for the same dataset and different years fall on the same line, figure 1.2. The same characteristics are observed for the distribution of the normalized lograte s 1.2. The growth is universal in time, and the group sizes distribution do not change from year to year.

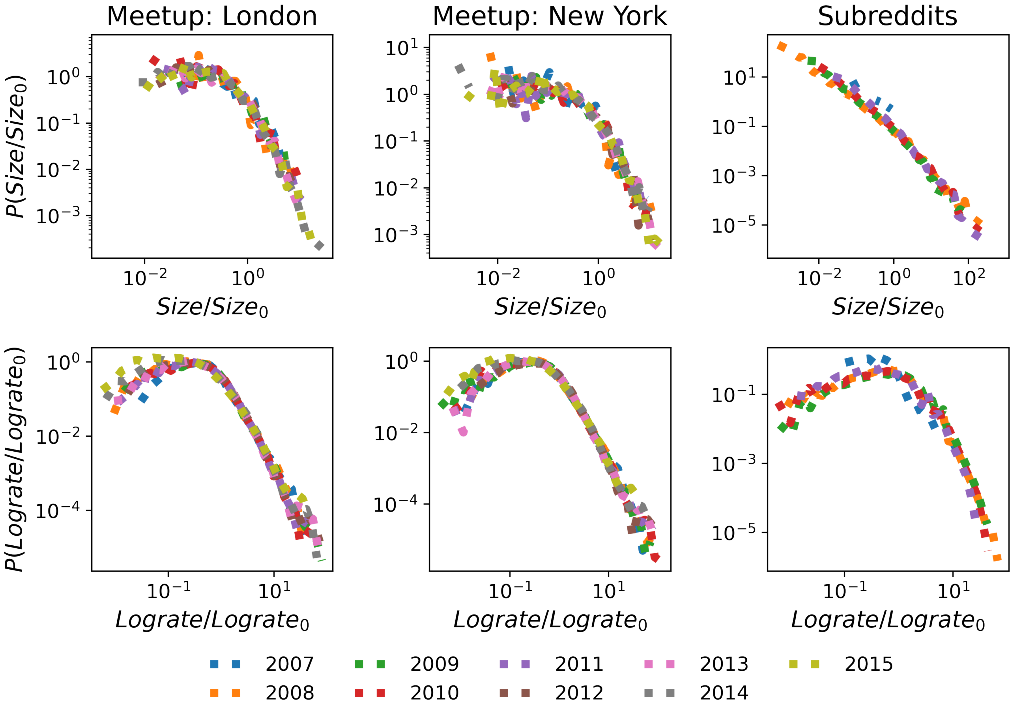


Figure 1.2: The figure shows the groups' sizes distributions and log-rates distributions. Each distribution collects groups founded in the same year and is normalized with its mean value. The group sizes are at the end of 2017 for meetups and 2011 for subreddits.

1.2 The model

The Meetup and Reddit engage members for different activities. Still, there are same underling processes for both systems. Each member can create new groups and join existing ones. Both systems grow in the number of groups and the number of users, and each user can belong to arbitrary number of groups. In the previous section we identified the universal patterns in the growth of social groups, but it appears that the growth can not be modeled with Gibrat law. The complex network models allow us to simulate the growth of these systems considering all types of the member's activities. Varying different linking rules we can identify how model parameters shape the growth process. When it comes to the user's choice of the group, it was shown that social connections play important role [6, 7]. On the other hand, user can be driven with personal interest. Diffusion between groups could be also enhanced with rich-get-richer phenomena, where users tend to join larger groups. Also, with complex network model we can easily incorporate the nonlinear growth in the number of users and groups, as they influence the structure and dynamics of the complex network [8, 9, 10].

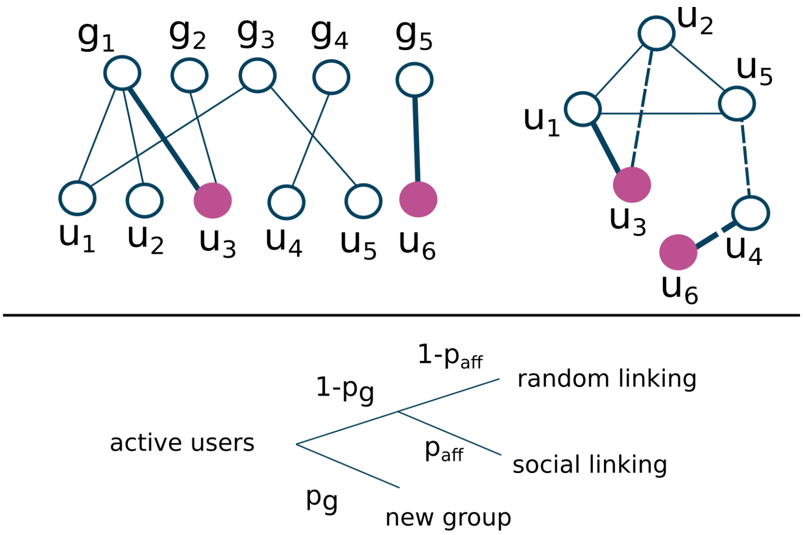

Figure 1.3: The top panel shows bipartite (member-group) and social (member-member) network. Filled nodes are active members, while thick lines are new links in this time step. In the social network dashed lines show that members are friends but still do not share same groups. The lower panel shows model schema. **Example:** member u_6 is a new member. First it will make random link with node u_4, and then with probability p_g makes new group g_5. With probability p_a member u_3 is active, while others stay inactive for this time step. Member u_3 will with probability $1 - p_g$ choose to join one of old groups and with probability p_{aff} linking is chosen to be social. As its friend u_2 is member of group g_1, member u_3 will also join group g_1. Joining group g_1, member u_3 will make more social connections, in this case it is member u_1.

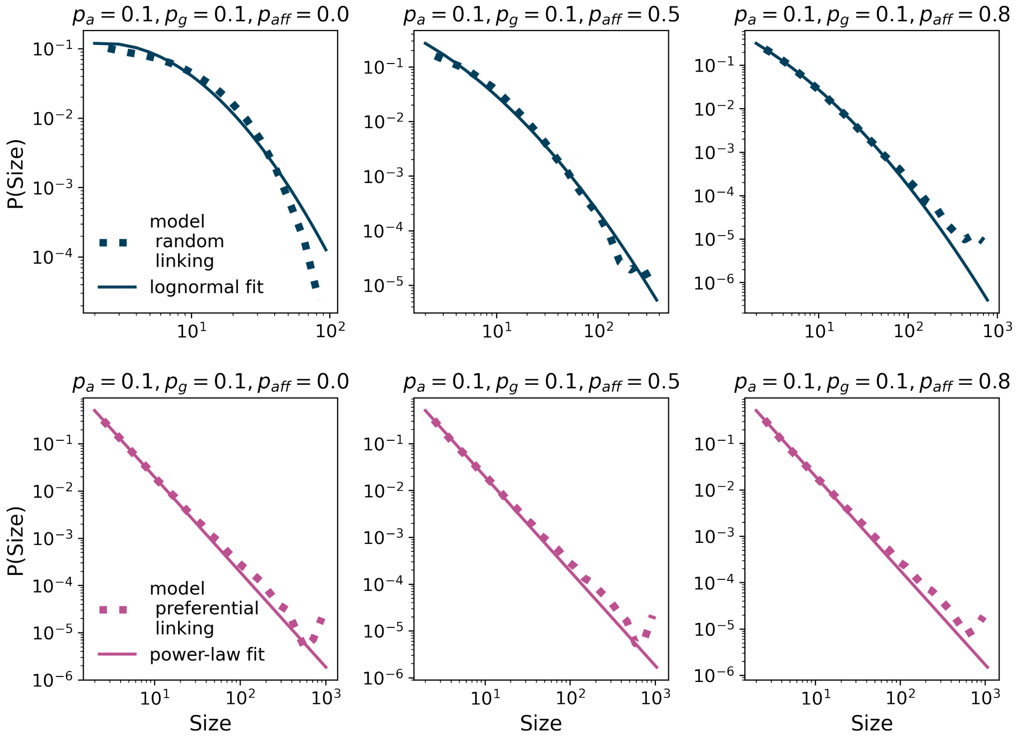

Figure 1.4: Groups sizes distributions for groups model, where at each time step the constant number of users arrive, $N = 30$ and old users are active with probability $p_a = 0.1$. Active users make new groups with probability $p_g = 0.1$, while we vary affiliation parameter p_{aff}. With probability, $1 - p_{aff}$, users choose a group randomly. The group sizes distribution (top row) is described with a log-normal distribution. With higher affiliation parameter, p_{aff}, distribution has larger width. The bottom row presents the case where with probability $1 - p_{aff}$ users have a preference toward larger groups. For all values of parameter p_{aff}, we find the power-law group sizes distribution.

1.3 Results

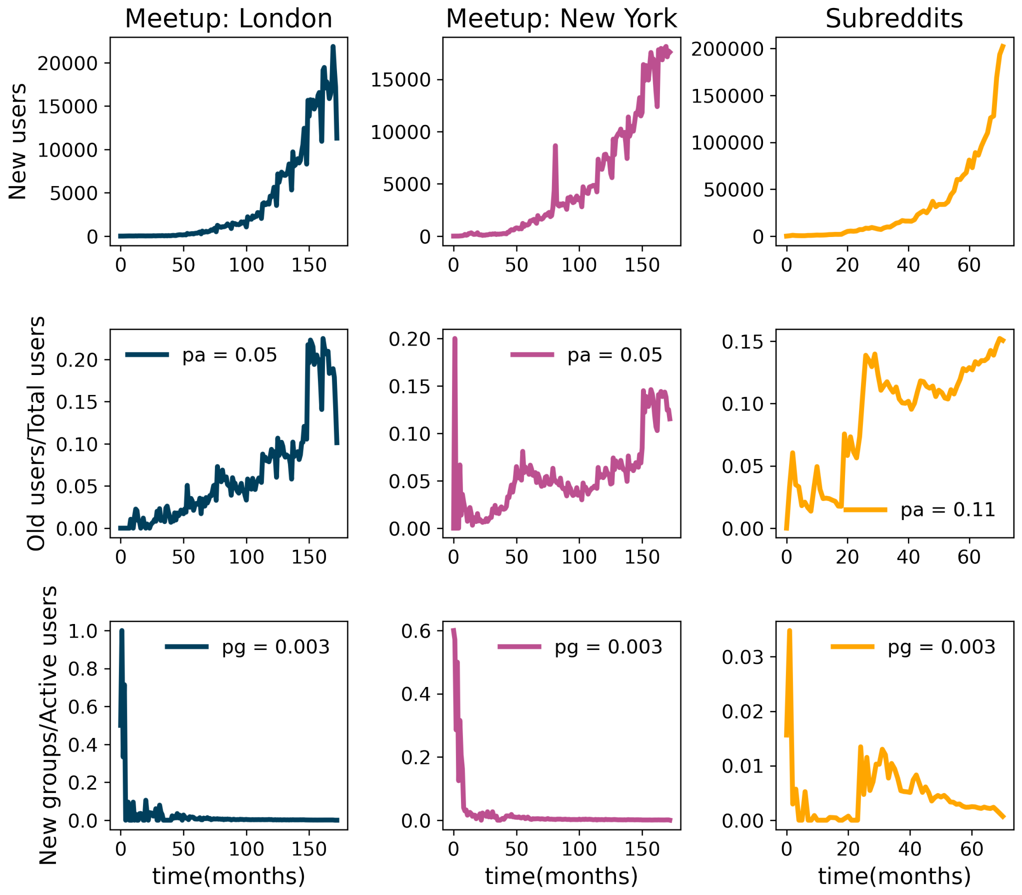

Figure 1.5: The time series of number of new members (top panel), ratio between old members and total members in the system (middle panel), and ratio between new groups and active members(bottom panel) for Meetup groups in London, Meetup groups in New York, and subreddits.

p_{aff}	JS cityLondon	JS cityNY	JS reddit2012
0.1	0.0161	0.0097	0.00241
0.2	0.0101	0.0053	0.00205

1.4 Distributions fit

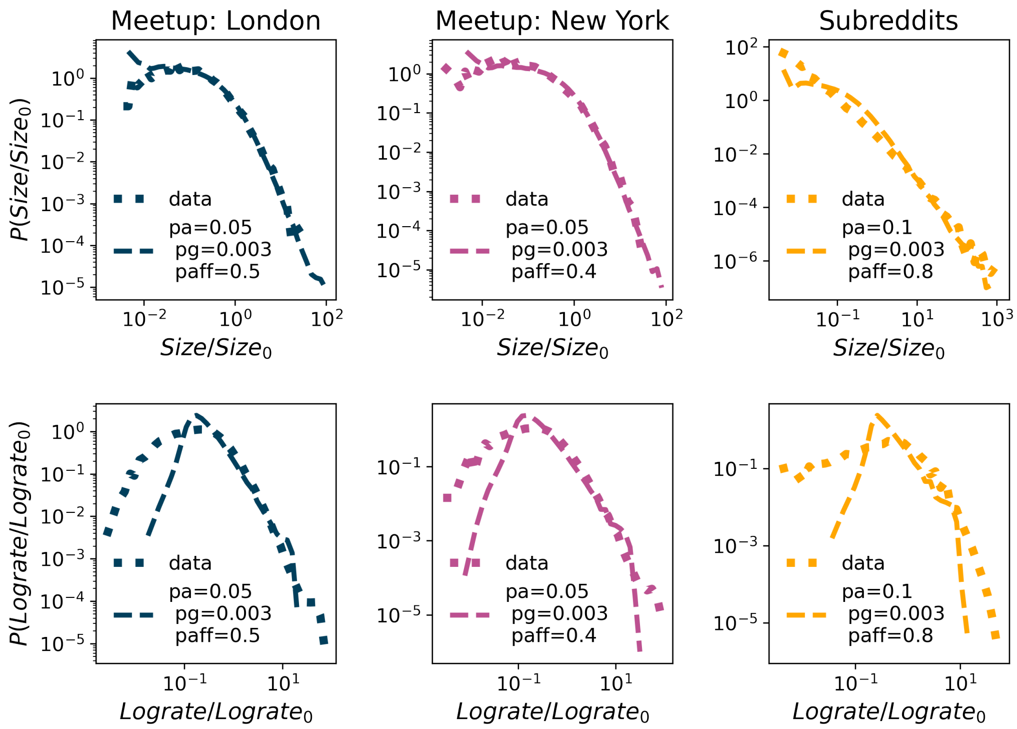

Figure 1.6: The comparison between empirical and simulation distribution for group sizes (top panel) and lograts (bottom panel).

Table 1.2: The likelihood ratio R and p-value between different candidates and **lognormal** distribution for fitting the distribution of **groups sizes** of Meetup groups in London, New York and in Reddit. According to these statistics, the lognormal distribution represents the best fit for all communities.

distribution	Meetup city London		Meetup city NY		Reddit	
	R	p	R	p	R	p
exponential	-8.64e2	8.11e-32	-8.22e2	6.63e-26	-3.85e4	1.54e-100
stretched exponential	-3.01e2	1.00e-30	-1.47e2	7.78e-8	-7.97e1	5.94e-30
power law	-4.88e3	0.00	-4.57e3	0.00	-9.39e2	4.48e-149
truncated power law	-2.39e3	0.00	-2.09e3	0.00	-5.51e2	2.42e-56

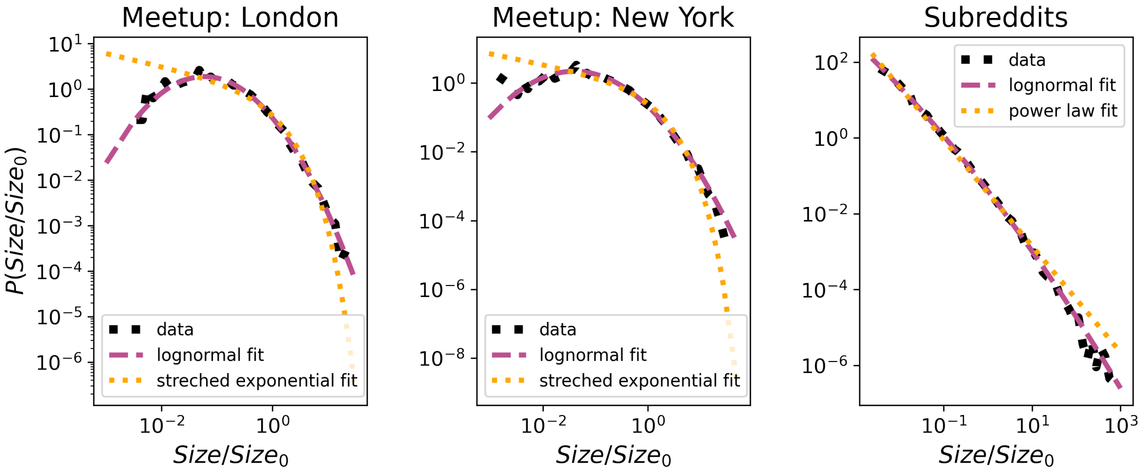

Figure 1.7: The comparison between log-normal and stretched exponential fit to London and NY data, and between log-normal and power law for Subreddits. The parameters for log-normal fits are 1) for city London $\mu = -0.93$ and $\sigma = 1.38$, 2) for city NY $\mu = -0.99$ and $\sigma = 1.49$, 3) for Subreddits $\mu = -5.41$ and $\sigma = 3.07$.

Table 1.3: The likelihood ratio R and p-value between different candidates and **lognormal** distribution for fitting the distribution of **simulated group sizes** of Meetup groups in London, New York and Reddit. According to these statistics, the lognormal distribution represents the best fit for all communities.

distribution	Meetup city London		Meetup city NY		Reddit	
	R	p	R	p	R	p
exponential	-6.27e4	0.00	-5.11e4	0.00	-1.26e5	7.31e-125
stretched exponential	-1.01e4	1.96e-287	-6.69e3	1.46e-93	-1.39e4	0.00
power law	-2.29e5	0.00	-3.73e5	0.00	-4.38e4	0.00
truncated power law	-9.28e4	0.00	-1.55e5	0.00	-9.12e4	0.00

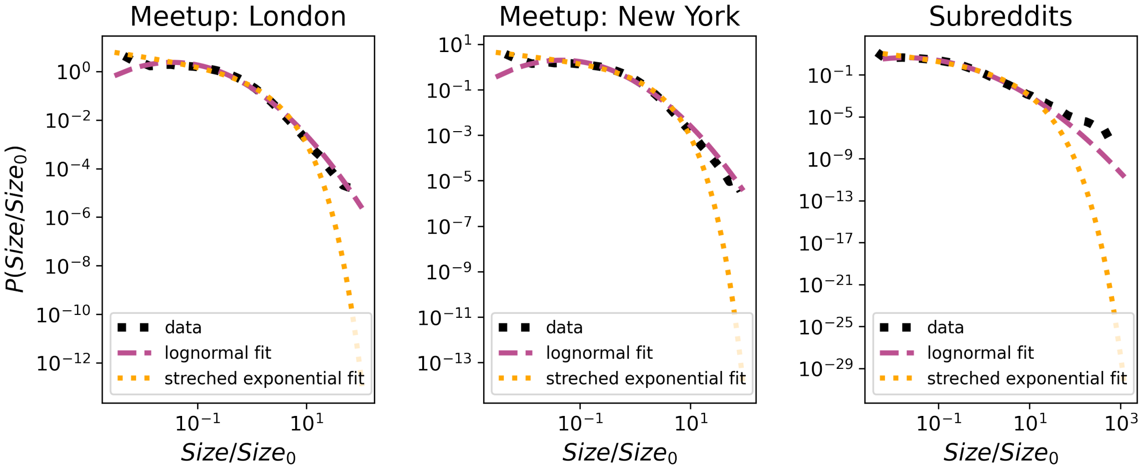

Figure 1.8: The comparison between lognormal and stretched exponential fit to simulated group sizes distributions. The parameters for log-normal fits are 1) for city London $\mu = -0.97$ and $\sigma = 1.43$, 2) for city NY $\mu = -0.84$ and $\sigma = 1.38$, 3) for Subreddits $\mu = -1.63$ and $\sigma = 1.53$.
